MACM 202 Assignment 1, Spring 2004

Michael Monagan

This assignment is worth 10% of your grade. It is due Wednesday January 21st at 10am. A late penalty of 20% will apply for each day late. The use of Maple on this assignment is compulsory. Do each question in a separate Maple worksheet. Hand in a printout of each worksheet. Attempt all questions.

Questions 1.5, 1.7, 1.12, 1.17, 1.18, 1.20 from the text and the following two.

Theorem 1 does not say what happens when $f'(x*) = \pm 1$. Let $f(x) = ax^2 + bx + c$ where $a \neq 0$. Find numerical values for a, b, c such that f(x) has a fixed point x* with |f'(x*)| = 1. Determine and explain the behaviour of the iteration on both sides of the fixed point.

Consider the polynomials

$$f_1(x) = x^8 - 1$$
, $f_2(x) = x^8 + 1$, $f_3(x) = x^8 - x - 1$, $f_4(x) = x^8 + x + 1$.

Factor each of the polynomials using the factor command. Solve each polynomial for its roots first using the solve command and then using the fsolve command. Notice that some roots are complex. Find out how to get fsolve to compute all 8 complex roots. Apply the evalf command to the values returned by the solve command to verify that they are the same as those computed by the fsolve command. Now explain what the solve command does. Explain why solve sometimes returns roots involving sines and cosines and RootOfs in the output.

Notes.

- 1. In question 1.5 use $r = 1.75 \times 10^{-4}$ not $1.74 \times 10^{+4}$ as in the text.
- 2. When you use Maple to draw graphs of functions, you must choose a reasonable domain for the plot. Also, in order to visually locate fixed points and determine their stability, please graph the function y = x on the same plot.
- 3. Questions 1.12, 1.17, 1.18, which ask you to *show* the location of any maxima, minima, and inflection points. Instead, compute where the maxima and minima are using Maple.
